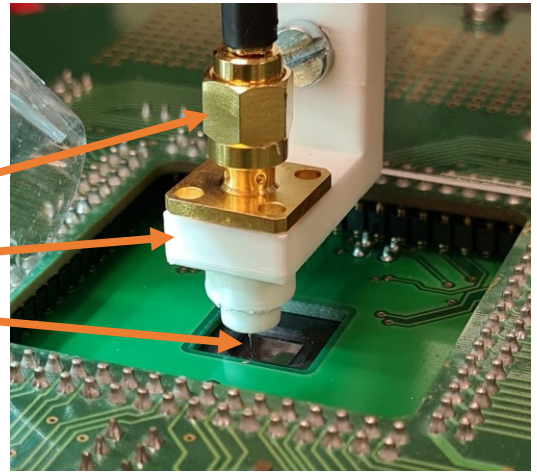
OBJECTIVES

- Introduce enhanced BBI platforms:
  - Better efficiency
  - More reproducible results
- Differential fault attack:
  - Hardware AES
  - Giraud’s DFA
- BBI fault model:
  - Charge extortion

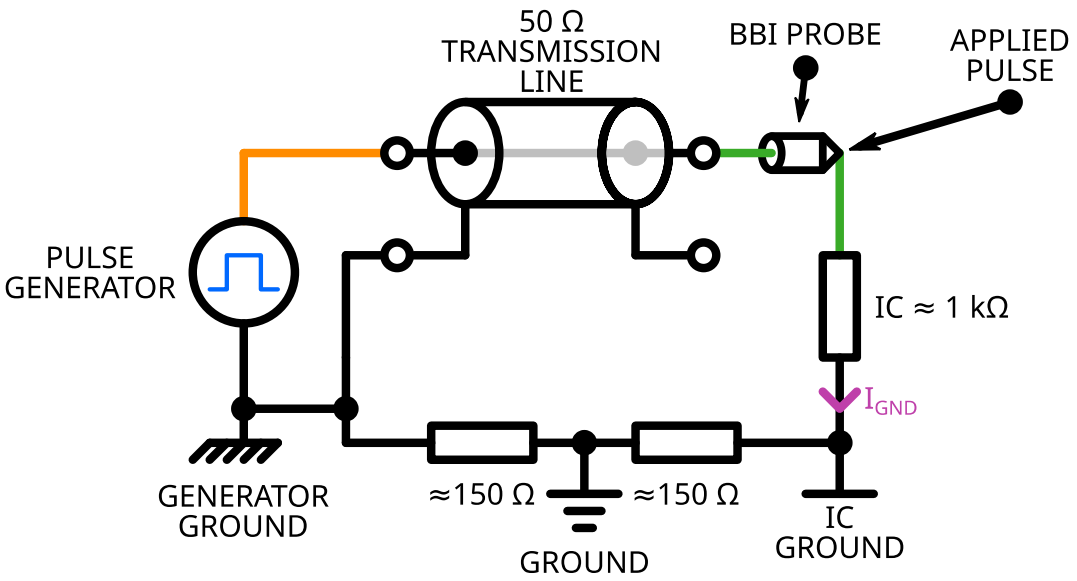
Test platform

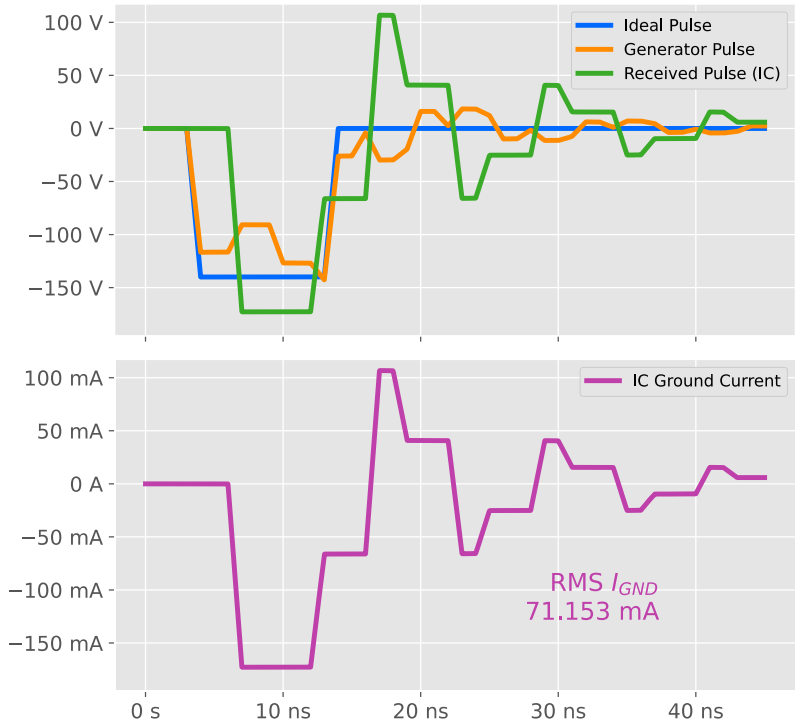
- AVTECH AVRK-4-B voltage pulse generator:
  - Amplitudes: ± 50 V to ± 750 V
  - Pulse widths: 6 ns to 20 ns
- Custom made BBI probes and support:
  - 3D-printed support
  - SMA connector
  - Pogo-pin
- STM32F439 32-bits microcontroller → hardware AES co-processor



BBI enhanced platforms

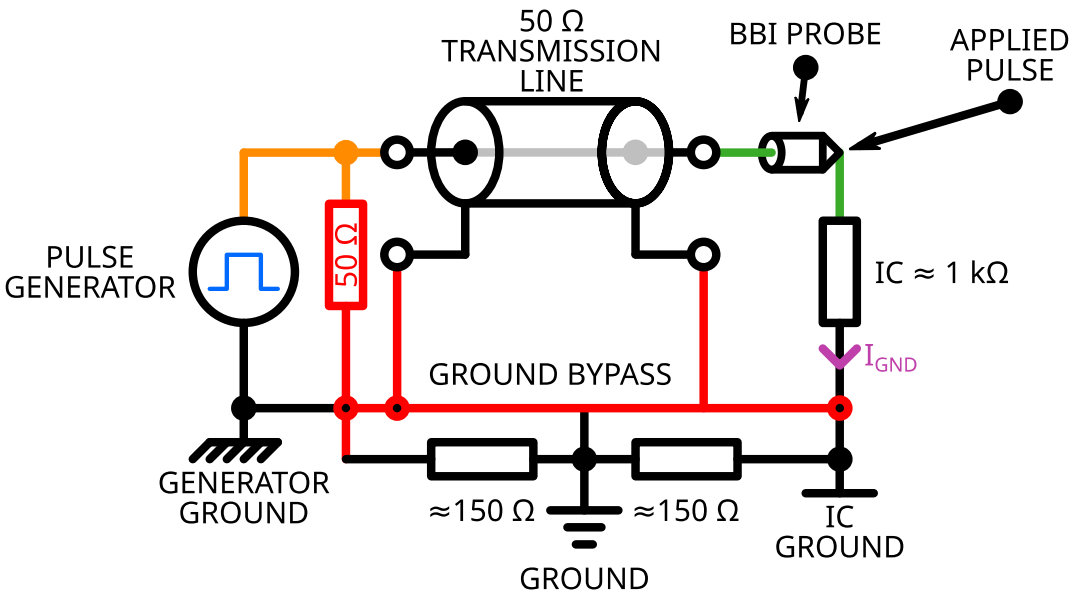
BBI in the state-of-the-art

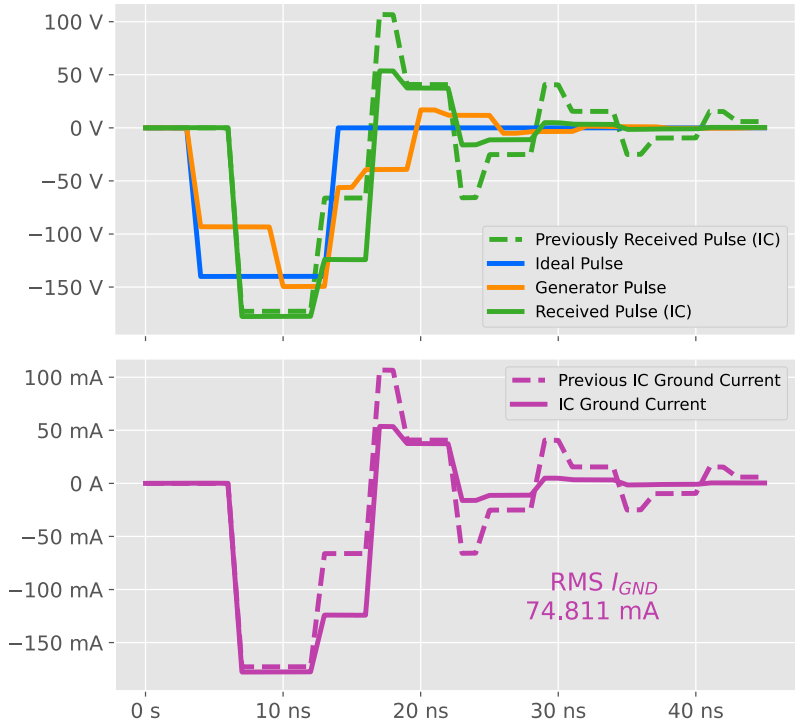




- Voltage setpoint not met:
  - Lot of ringing → impedance mismatch
  - Low-quality equipment grounding

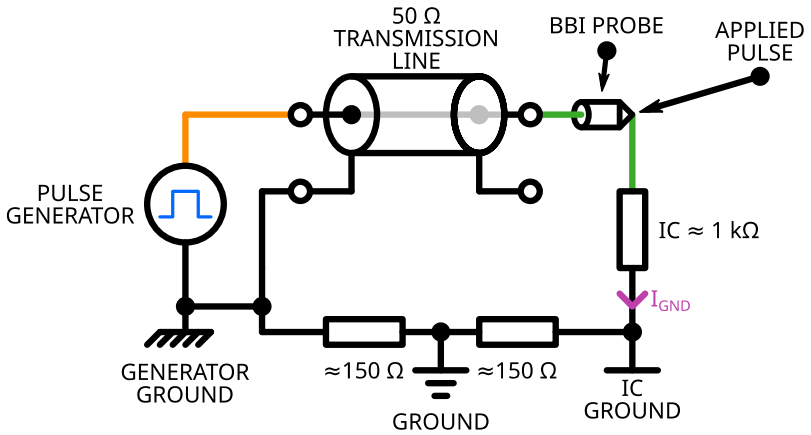
BBI enhanced platform

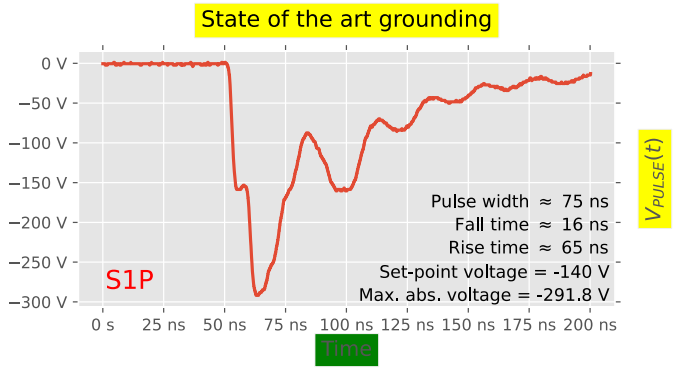


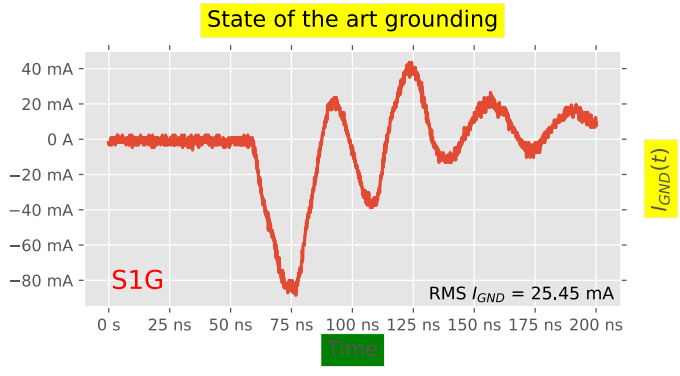


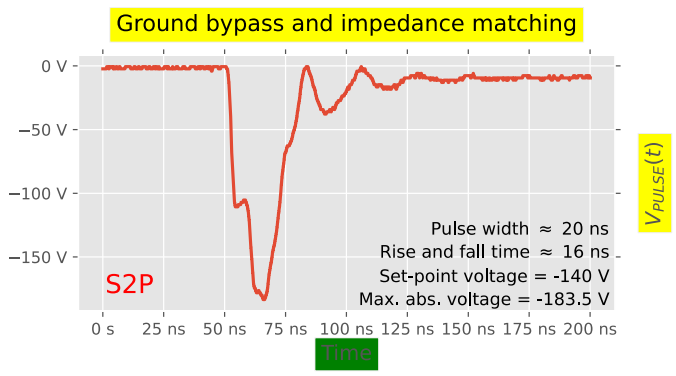
- Voltage setpoint closer to expectations
- Less ringing

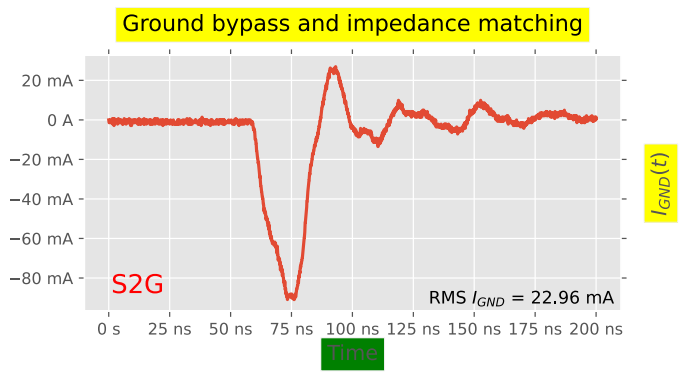
Experimental measurements









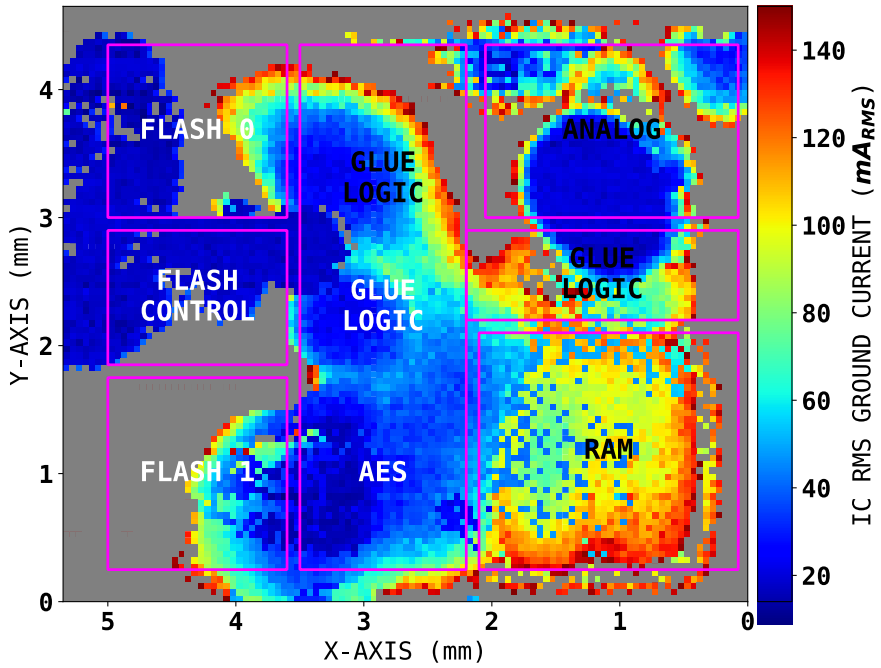


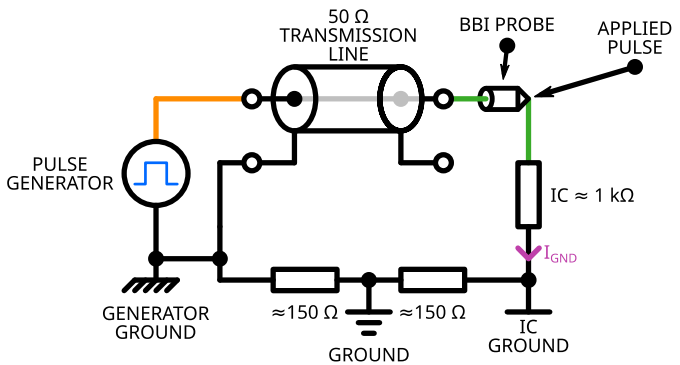
Voltage pulse generator output:
Setpoint: -140 V ; 20 ns

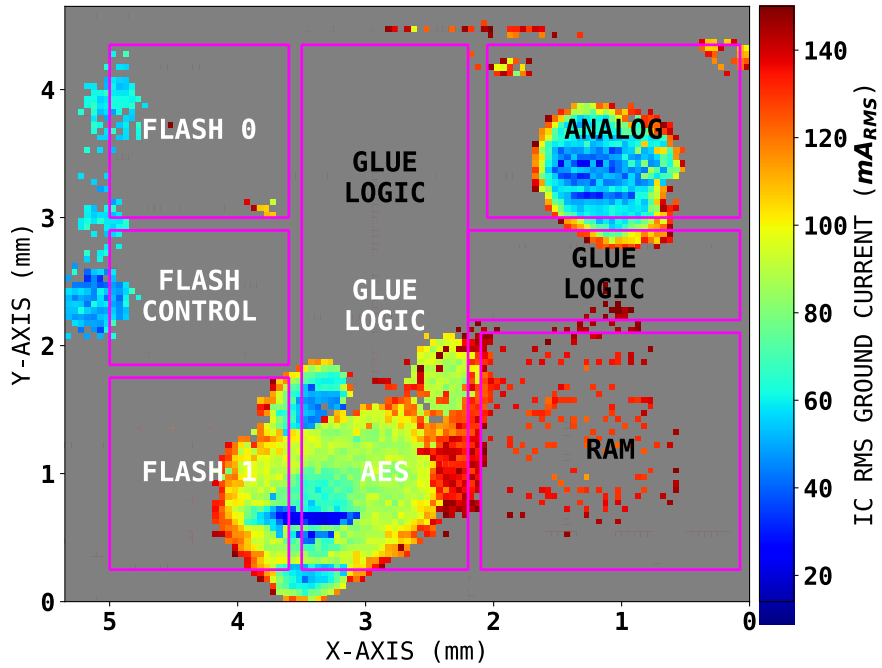
IC ground current

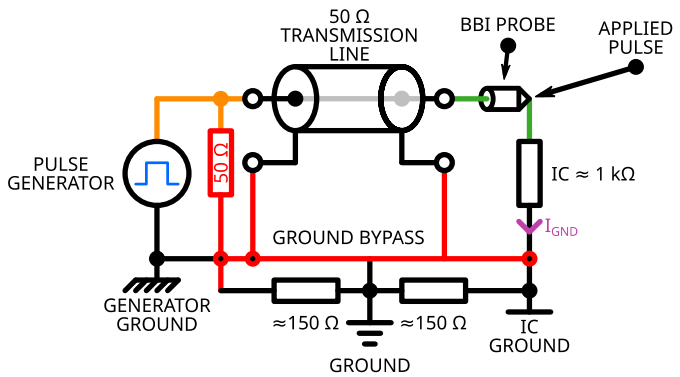
Enhancements in practice

IC fault susceptibility analysis



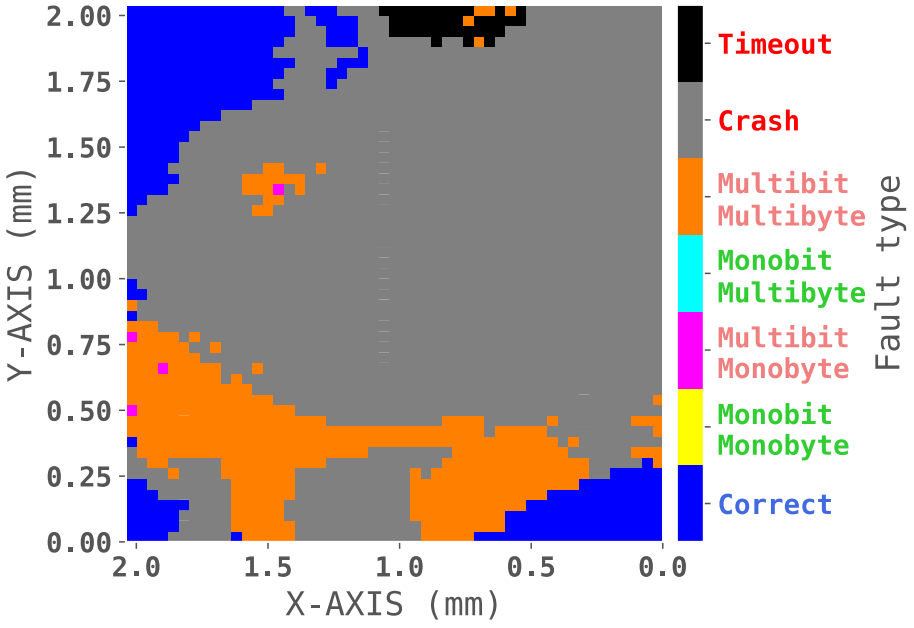


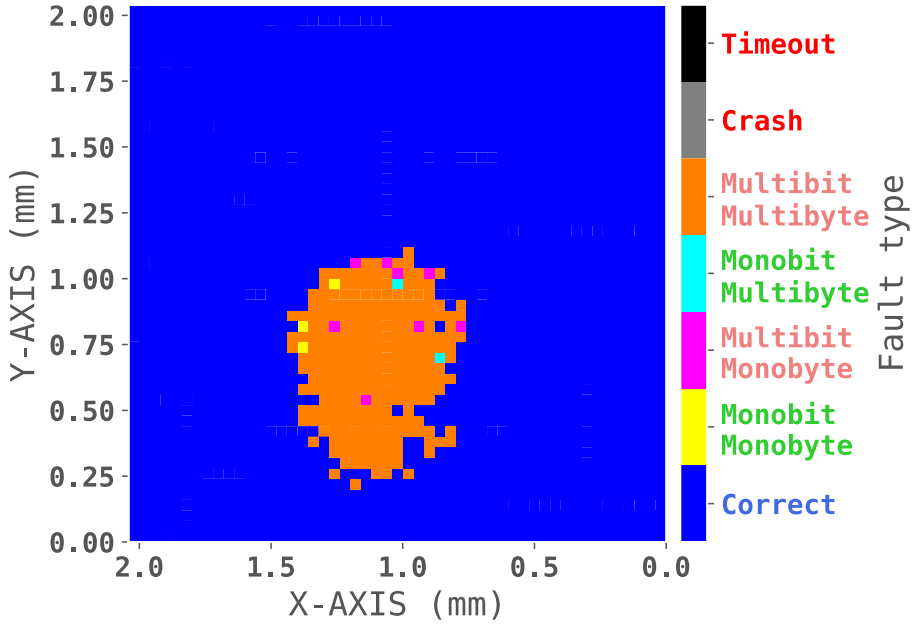


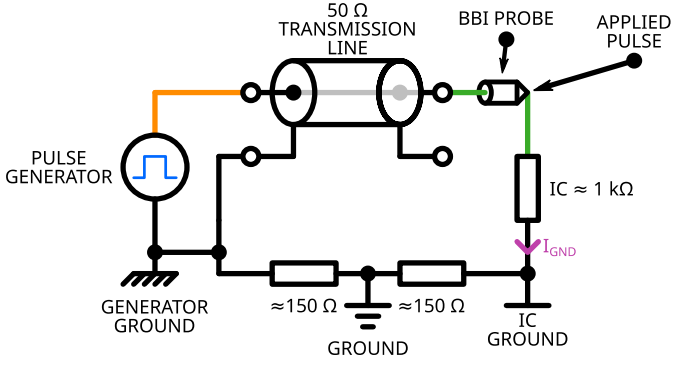


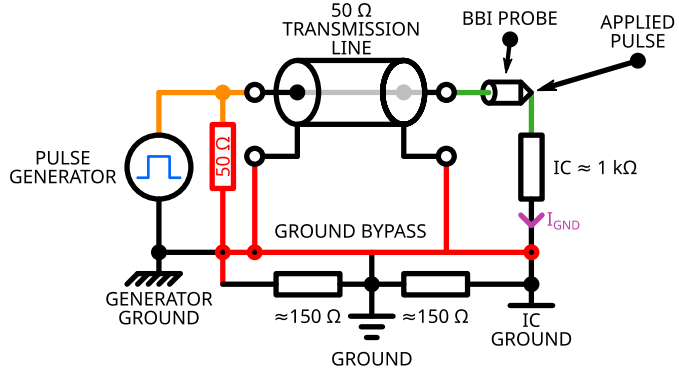
Differential fault attack in practice

Bit-fault attack on AES-128 → Giraud, 2002

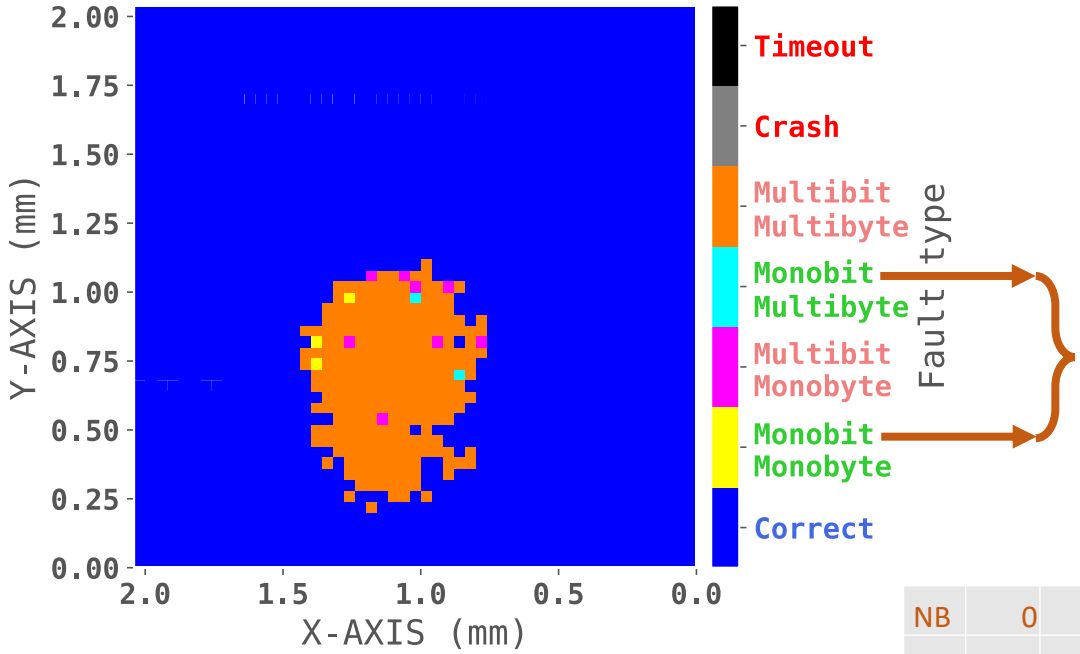








Differential fault attack in practice



- Monobit faults on single bytes
- Monobit faults on multiple bytes
- Successful Giraud attack

Valid faults for Giraud's monobit DFA

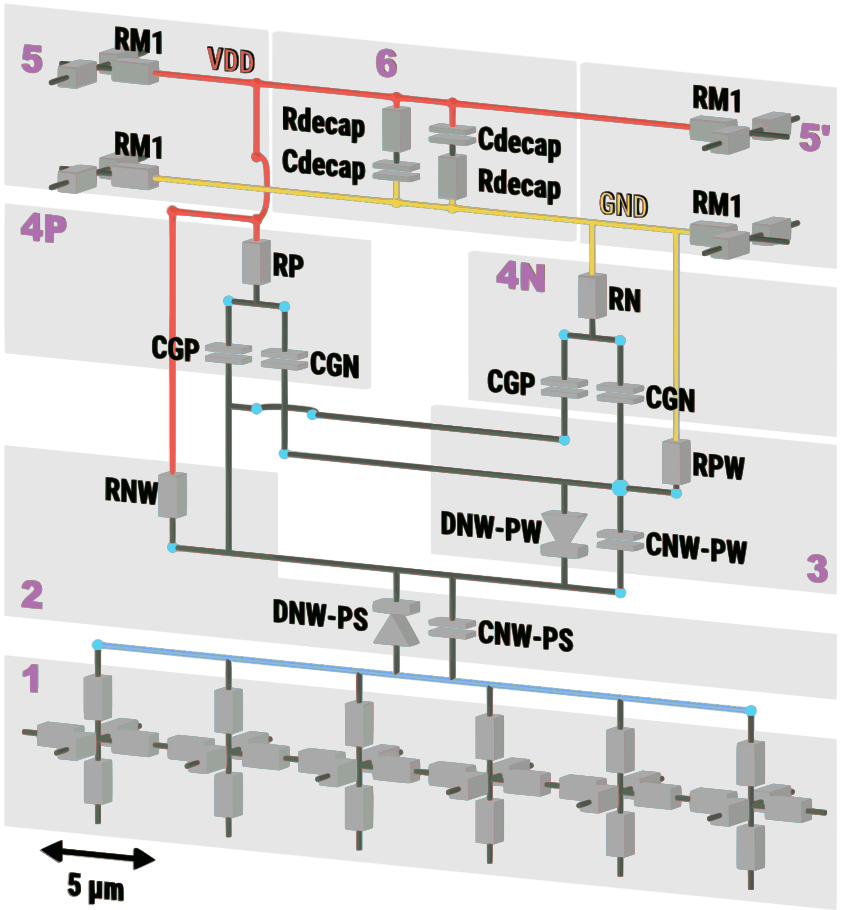
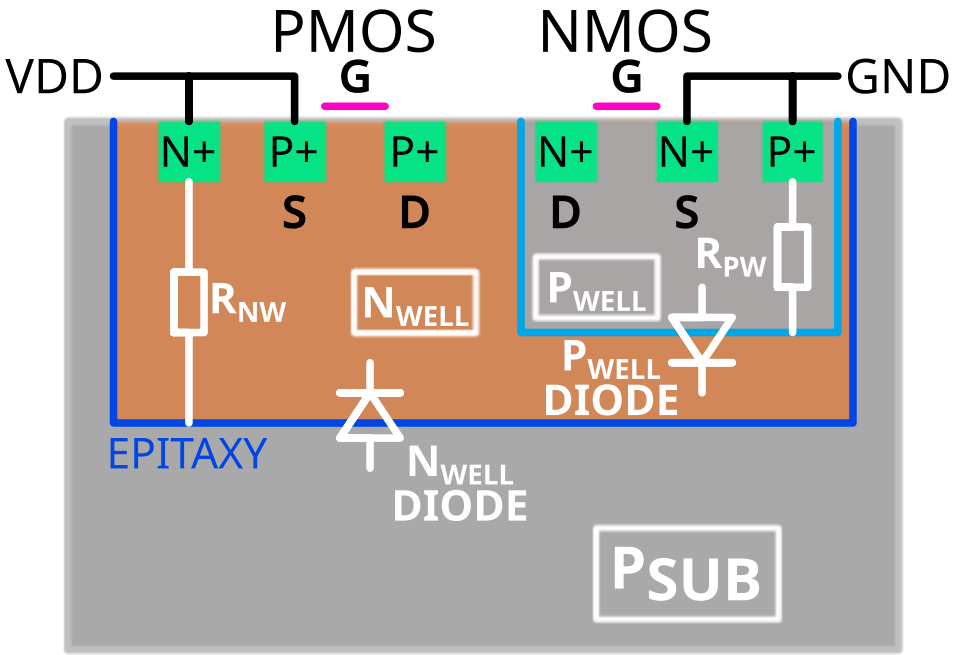
From more complex simulation models to fault model

Complex IC models: Triple-Well

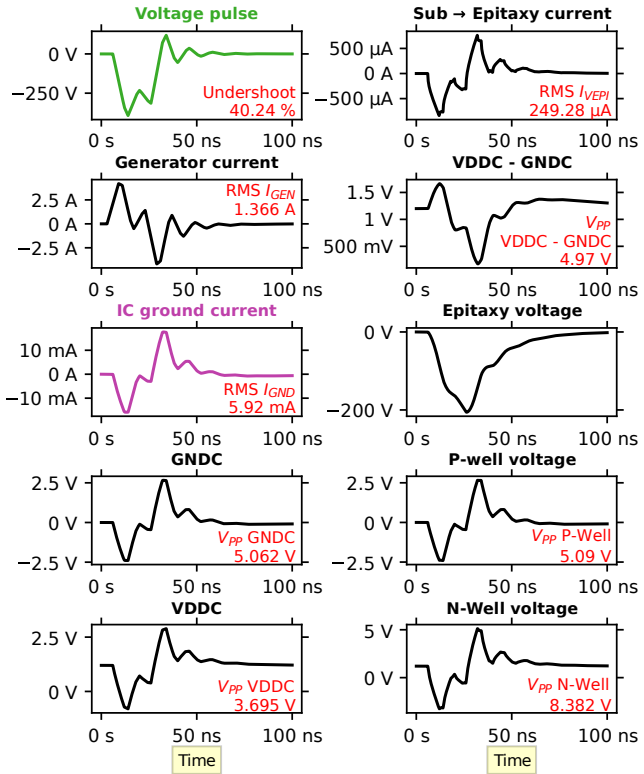


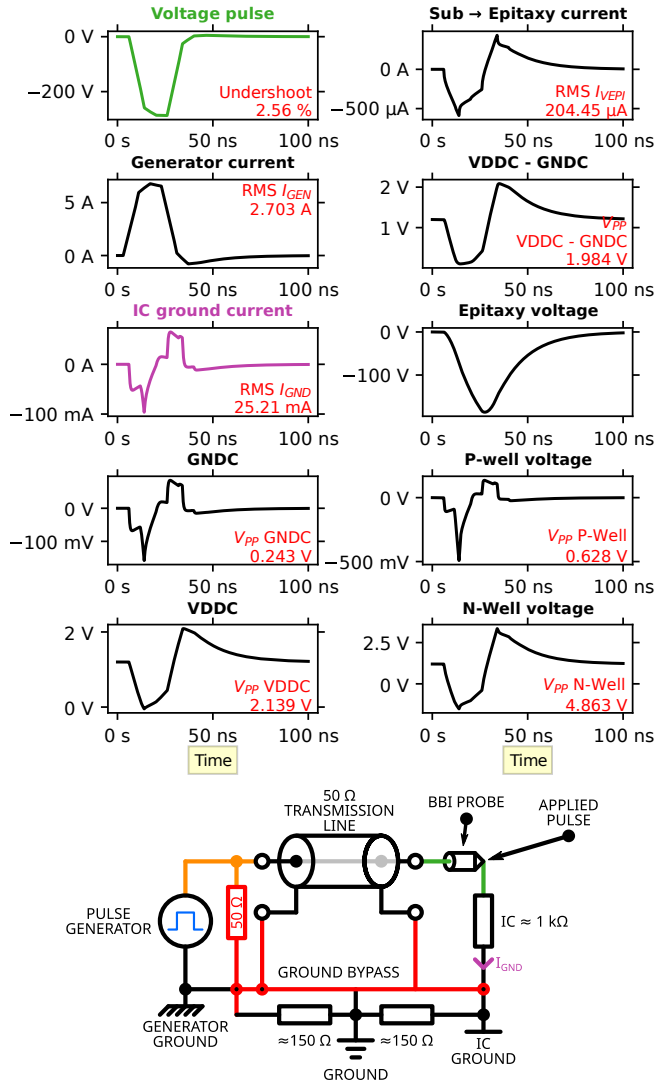
Standard-cell segment



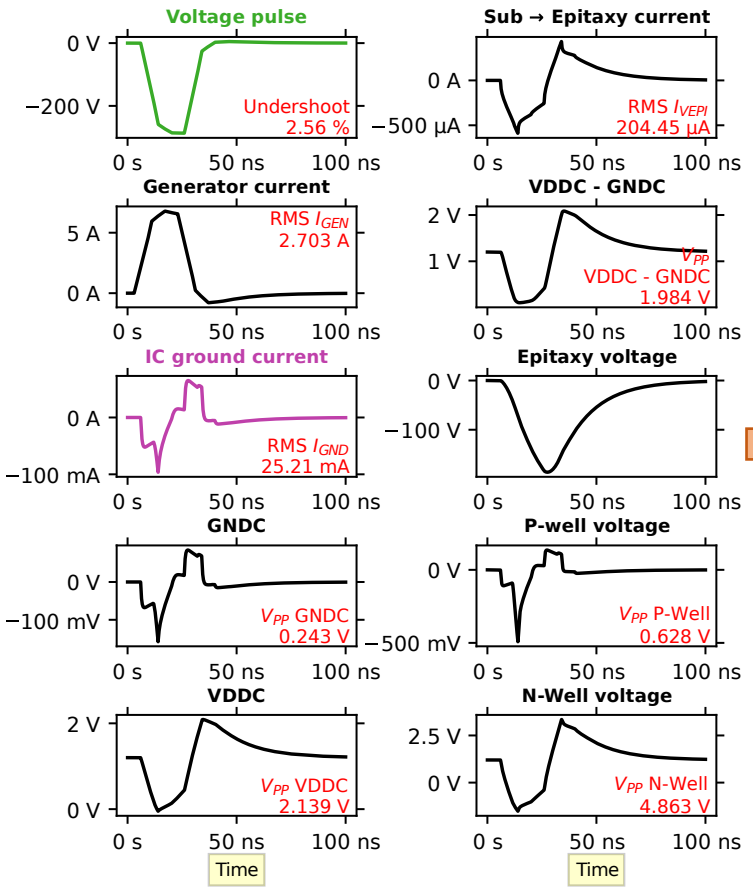
Logic inverter

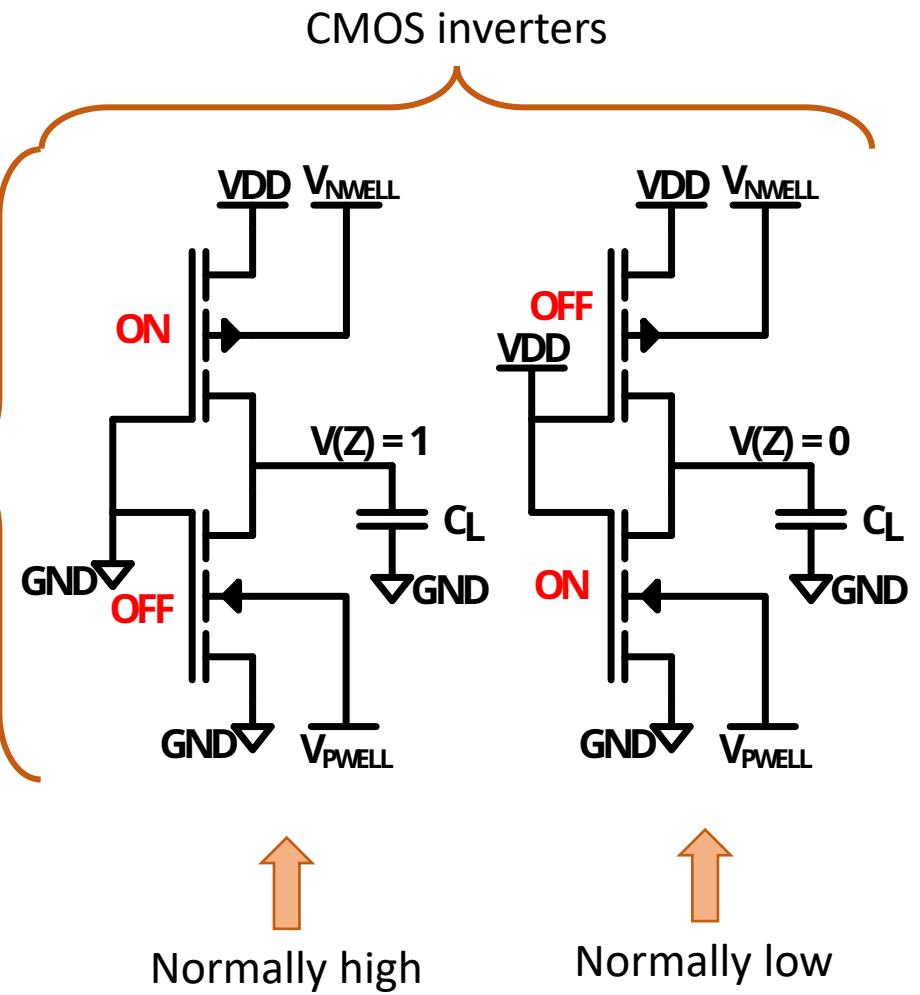
Effect of enhancements on a Triple-Well IC





CMOS logic gates evaluation

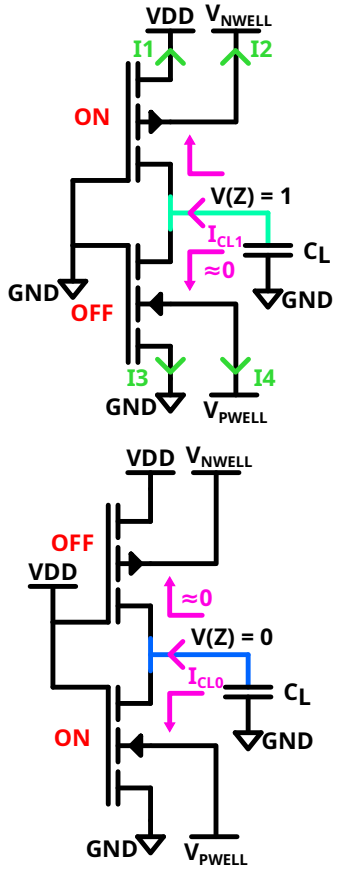


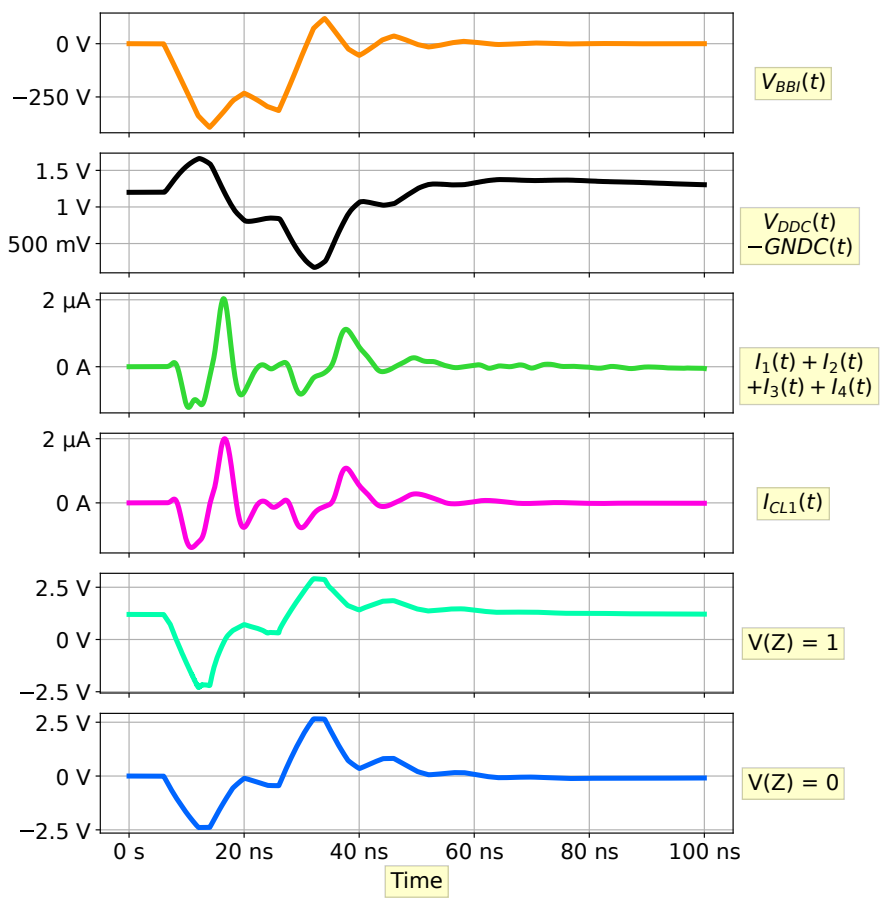


BBI impact on CMOS logic gates

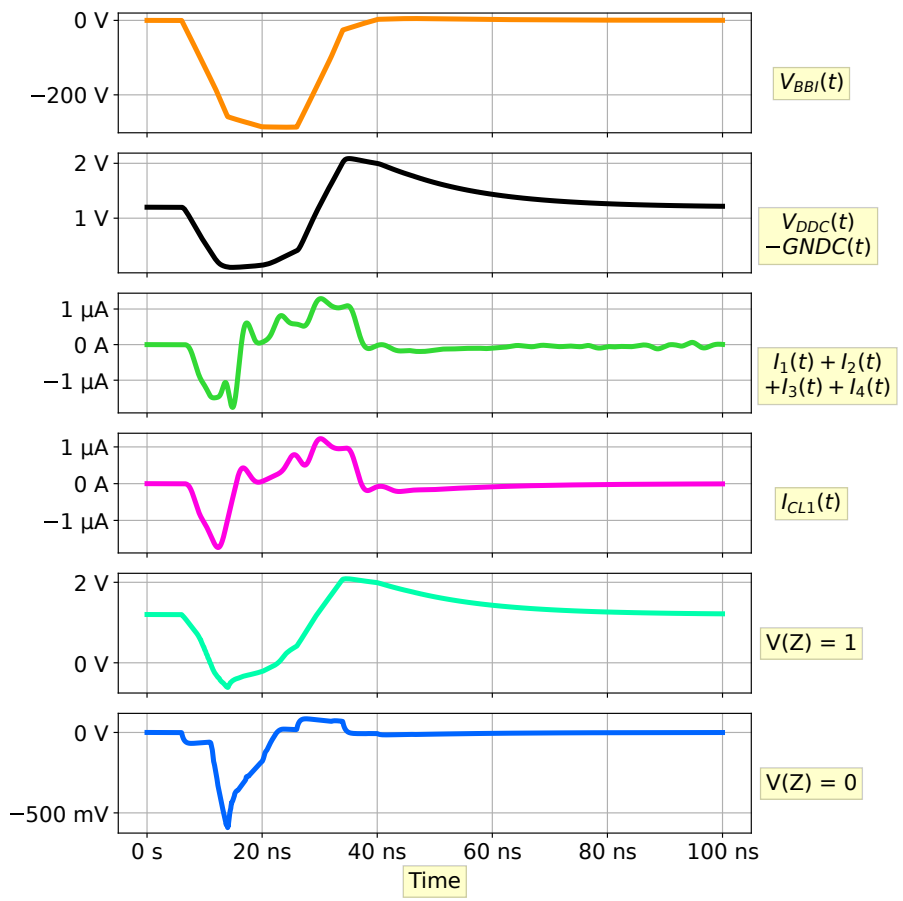
Normally High

Normally Low





State-of-the-art



Enhanced

Conclusion

- Enhanced BBI platforms:
  - Generator impedance matching
  - Platform parameters requirements met (PW, voltage…)
  - Better repeatability
  - Giraud’s single-bit DFA feasible
  - New step in simulation flow → logic gates disturbances simulations
